

1 Vector Spaces

- Reading: Gallian Ch. 19
- Today's main message: linear algebra (as in Math 21) can be done over any field, and most of the results you're familiar with from the case of \mathbb{R} or \mathbb{C} carry over.
- **Def:** A *vector space* over a field F is a set V with two operations $+$: $V \times V \rightarrow V$ (vector addition) and \cdot : $F \times V \rightarrow V$ (scalar multiplications) that satisfy the following properties:
 1. V is an abelian group under $+$.
 2. $(ab) \cdot v = a \cdot (b \cdot v)$ for all $a, b \in F$ and $v \in V$.
 3. $1 \cdot v = v$ for all $v \in V$.
 4. $a \cdot (v + w) = a \cdot v + a \cdot w$ for all $a \in F$ and $v, w \in V$.
 5. $(a + b) \cdot v = a \cdot v + b \cdot v$ for all $a, b \in F$ and $v \in V$.
- A vector space has more structure than an abelian group, but less structure than a ring (only multiplication by scalars, not multiplication of arbitrary pairs of elements of V).
- **Examples and Nonexamples:**
 - $V = F^n$
 - $V = \mathbb{C}, F = \mathbb{R}$
 - $V = \mathbb{Z}^n, F = \mathbb{Z}_2$
 - $V = F[x]$
 - $V = F[x]/\langle p(x) \rangle$

¹These notes are copied mostly verbatim from the lecture notes from the Fall 2010 offering, authored by Prof. Salil Vadhan. I will attempt to update them, but apologies if some references to old dates and contents remain.

– $V = R$ for a ring R containing F .

- **Def:** Let V be a vector space over of F . Vectors $v_1, \dots, v_n \in V$ are *linearly independent* iff for every $c_1, \dots, c_n \in F$, if $c_1v_1 + \dots + c_nv_n = 0$, then $c_1 = \dots = c_n = 0$. The vectors v_1, \dots, v_n form a *basis* for V iff they are linearly independent and $\text{Span}(v_1, \dots, v_n) = V$, where $\text{Span}(v_1, \dots, v_n) = \{c_1v_1 + \dots + c_nv_n : c_1, \dots, c_n \in F\}$.

- **Examples of bases:**

- $(1, 0, 0, \dots, 0), (0, 1, 0, \dots, 0), \dots, (0, 0, 0, \dots, 1)$ is a basis for F^n for every field F .
- **Q:** Is $(1, 1, 0), (1, 0, 1), (0, 1, 1)$ always a basis for F^3 ?
- Bases for other examples above?

- **Def:** The *dimension* of a vector space V over F is the size of the largest set of linearly independent vectors in V . (different than Gallian, but we'll show it to be equivalent)

- A measure of “size” that makes sense even for infinite sets.

- **Prop:** Every finite-dimensional vector space has a basis consisting of $\dim(V)$ vectors. Later we'll see that all bases have exactly $\dim(V)$ vectors.

Proof: Let v_1, \dots, v_k be the largest set of linearly independent vectors in V (so $k = \dim(V)$). To show that this is a basis, we need to show that it spans V . Let w be any vector in V . Since v_1, \dots, v_k, w has more than $\dim(V)$ vectors, this set must be linearly dependent, i.e. there exists constants $c_1, \dots, c_k, d \in F$, not all zero, such that $c_1v_1 + \dots + c_kv_k + dw = 0$. The linear independence of v_1, \dots, v_k implies that $d \neq 0$. Thus, we can write $w = (c_1/d_1)v_1 + \dots + (c_k/d_k)v_k$. So every vector in V is in the span of v_1, \dots, v_k .

- **Q:** What are the dimensions of the above examples?

- **Corollaries:**

- If V is an n -dimensional vector space over a finite field F , then $|V| = |F|^n$.
- If E is a finite field and F is a subfield of E , then $|E| = |F|^n$ for some $n \in \mathbb{N}$. (Much stronger than Lagrange, which only says $|F|$ divides $|E|$.)
- if E is a finite field of characteristic p , then $|E| = p^n$ for some $n \in \mathbb{N}$. (Shown on PS7 using Classification of Abelian Groups.)

2 Maps Between Vector Spaces

- **Def (vector-space homomorphisms):** Let V and W be two vector spaces over F . A function $f : V \rightarrow W$ is a *linear map* iff for every $x, y \in V$ and $c \in F$, we have

1. $f(x + y) = f(x) + f(y)$ (i.e. f is a group homomorphism), and
2. $f(cx) = cf(x)$.

f is an *isomorphism* if f is also a bijection. If there is an isomorphism between V and W , we say that they are *isomorphic* and write $V \cong W$.

- **Prop:** Every n -dimensional vector space V over F is isomorphic to F^n .

Proof: Let v_1, \dots, v_n be a basis for V .

Then an isomorphism from F^n to V is given by:

- **Matrices:** A linear map $f : F^n \rightarrow F^m$ can be described uniquely by an $m \times n$ matrix M with entries from F .
 - $M_{ij} = f(e_j)_i$, where $e_j = (000 \dots 010 \dots 00)$ has a 1 in the j 'th position.
 - For $v = (v_1, \dots, v_n) \in F^n$, $f(v)_i = f(\sum_j v_j e_j)_i = \sum_j v_j f(e_j)_i = \sum_j M_{ij} v_j = (Mv)_i$, where Mv is matrix-vector product.
 - Matrix multiplication \leftrightarrow composition of linear maps.
 - If $n = m$, then f is an isomorphism $\Leftrightarrow \det(M) \neq 0$.
 - Solving $Mv = w$ for v (when given M and $w \in F^m$) is equivalent to solving a linear system with m variables and n unknowns.
- **Example:** $f : \mathbb{Z}_3^3 \rightarrow \mathbb{Z}_2^3$ given by $f(v_1, v_2, v_3) = (v_1 + 2v_2, 2v_1 + v_3)$.

- **Thm:** If $f : V \rightarrow W$ is a linear map, then $\dim(\ker(f)) + \dim(\text{im}(f)) = \dim(V)$.

Proof: omitted.

- When F finite, this says $|V| = |F|^{\dim(V)} = |F|^{\dim(\ker(f))} \cdot |F|^{\dim(\text{im}(f))} = |\ker(f)| \cdot |\text{im}(f)|$, just like for group homomorphisms!
- **Corollaries:**
 - $F^n \not\cong F^m$ if $m \neq n$.
 - All bases of a vector space have the same size.
 - A homogenous linear system $Mv = 0$ for a given $m \times n$ matrix M always has a nonzero solution v if $n > m$ (more variables than unknowns).
- **Computational issues:** For $n \times n$ matrices over F ,
 - Matrix multiplication can be done with $O(n^3)$ operations in F using the standard algorithm.
 - The determinant and inverse, and solving a linear system $Mv = w$ can be done using $O(n^3)$ operations in F using Gaussian elimination. (For infinite fields, need to worry about the size of the numbers, or accuracy if doing approximate arithmetic. No such problem in finite fields.)
 - Asymptotically fastest known algorithms run in time $O(n^{2.376})$. Whether time $O(n^2)$ is possible is a long-standing open problem.

3 Application to Extension Fields

- Reading: parts of Gallian Ch. 21
- **Def:** E is an *extension field* of F if F is a subfield of E . The *degree of E over F* is the dimension of E as a vector space over F , and is denoted $[E : F]$. E is a *finite extension* if $[E : F]$ is finite.
- **Examples:**
 - $[\mathbb{C} : \mathbb{R}] =$
 - $[F[x]/\langle p(x) \rangle : F] =$
 - $[\mathbb{F}(\alpha) : \mathbb{F}] =$
- **Thm 21.5:** If K is a finite extension of E , and E is a finite extension of F , then $[K : F] = [K : E][E : F]$.
- **Example:** The splitting field of $x^8 - 1$ over \mathbb{Q} , i.e. $\mathbb{Q}(\omega) = \mathbb{Q}(i)(\omega)$, where $\omega = e^{2\pi i/8}$.

- **Proof:**

- **Corollary:** If E is a finite extension of F and $\alpha \in E$, then α is algebraic over F and its minimal polynomial has degree dividing $[E : F]$.

4 Finite Fields

- **Reading:** Gallian Ch. 22
- Recall (ps7): only possible sizes for finite fields are prime powers p^n .
- **Thm 22.1 (all the finite fields):** For every prime p and $n \in \mathbb{N}$,
 1. (Existence) There exists a finite field of order p^n , denoted \mathbb{F}_{p^n} or $\text{GF}(p^n)$ (for “Galois field”).
 2. (Uniqueness) Every two finite fields of order p^n are isomorphic.

Proof: Let F be splitting field of $f(x) = x^{p^n} - x$ over \mathbb{Z}_p , $F' =$ roots of $f(x)$ in F .

– Claim 1: F' is a subfield of F (and hence $F' = F$ by def of splitting field).

– Claim 2: the roots of $f(x)$ are all distinct in F .

– Claim 3: every finite field of order p^n is a splitting field of $f(x)$.

• **Thm 22.2 (group structure):**

1. The additive group of \mathbb{F}_{p^n} is isomorphic to \mathbb{Z}_p^n .
2. The multiplicative group $\mathbb{F}_{p^n}^*$ is cyclic. (A generator of the multiplicative group is called a *primitive element* of \mathbb{F}_{p^n} .)

Proof:

1.

2.

• **Corollaries:**

1. For every n , there is an element of \mathbb{F}_{p^n} of degree n over \mathbb{Z}_p .

2. For every n , there is an irreducible polynomial of degree n in $\mathbb{Z}_p[x]$.

Proof:

Thus, instead of constructing \mathbb{F}_{p^n} as a splitting field by adjoining several roots, we can take a *single* irreducible polynomial $f(x)$ of degree n and $\mathbb{Z}_p[x]/\langle f(x) \rangle \cong \mathbb{F}_{p^n}$.

• **Examples:**

1. $\mathbb{F}_{7^3} \cong \mathbb{Z}_7[x]/\langle x^3 + 2 \rangle$.
2. $\mathbb{F}_{7^3} \cong \mathbb{Z}_7[x]/\langle x^3 + x^2 + 1 \rangle$.
3. Adding and multiplying $x^2 + 5$ and $3x + 2$ in above representations of \mathbb{F}_{7^3} :

• **Computational Issues:**

- Computations in the finite field \mathbb{F}_{p^n} can be done efficiently given the prime p and an irreducible polynomial $f(x)$ over \mathbb{Z}_p of degree n .

Addition:

Multiplication:

Inverses:

- How to find p and $f(x)$?
 1. Choose randomly and test for primality/irreducibility (which can be done in polynomial time). Primes and irreducible polynomials have noticeable density (PS10), so this doesn't take too many trials.
 2. Use a small value of p (e.g. $p = 2$) and known explicit irreducible polynomials, e.g. $f(x) = x^{2 \cdot 3^\ell} + x^{3^\ell} + 1$.
