

Polynomial Method & Variations - IITB

Thursday, December 22, 2016 10:50 PM

Polynomial Method

Problem

- $S \subseteq \mathbb{F}^n$ (\mathbb{F} = field)
- S has nice algebraic / geometric property P
- $\mu(S)$ - combinatorial parameter

Paradigm

- $\mu(S) < k$

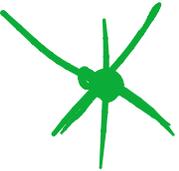

- Assume $\mu(s) < k$
- Prove ^{poly} $\exists Q$ s.t. $Q(s) = 0$
- Use low-deg of Q & property?
- to prove Q is zero in
"unexpected" ways
- Get contradiction \square

Remarkably Effective!

- Bounds of # polynomials through
small set of points (RS deuring)

- Bounds on # lines through small
set of points (Kakeya Nikodym)

- Bounds on joints  in 3-d
through small # lines

- Distinct distances ...

- Capset Problem

- Property testing

I. REED - SOLOMON DECODING

Context: Message \equiv Polynomial

Encoding \equiv Sequence of Evaluations

Decoding \equiv "find poly consistent with many points"

Question: How many polynomials?

Concrete Problem:

Given: $(x_1, y_1), (x_2, y_2) \dots (x_n, y_n) \quad x_i, y_i \in \mathbb{F}$
+ parameters d, t

Question: $p \in \mathbb{F}^{\leq d}[x]$ is t -agreeing if

$$|\{i \mid p(x_i) = y_i\}| \geq t$$

• \exists bound: $|\{p \mid p \text{ } t\text{-agreeing}\}| \leq ?$

~~————— X —————~~

Solution:

1. \exists m s.t. \forall $p \in \mathbb{F}^{\leq d}$ \bigwedge in x, y s.t.

Proofs of ①, ②, ③

①: $R(x) \equiv Q(x, p(x))$ has $\deg. \leq \Delta(d+1)$

$R(x_i) = 0$ if $p(x_i) = y_i$

$\Rightarrow R \equiv 0 \Rightarrow y - p(x) \mid Q(x, y)$

② Counting: # coefficients of $Q = (d+1)^2 > n$
= # constraints

"Homogenous linear system of small rank
has many solutions"

③ $Q(x,y)$ of deg Δ has at most Δ factors of the form $y - p(x)$.

State of art: know bounds for $t > \sqrt{dn}$;

But open for $t \leq \sqrt{dn}$.

- Proof 1: Jaikumar "Zarankiewicz"
Radhakrishnan method

- Proof 2: Guruswami + S. "multiplicity"

II. Nikodym Sets

- $S \subseteq \mathbb{F}_2^n$

- $\bar{S} = S \cup \left(\bigcup_{\ell} \{ \text{line } \ell \mid |\ell \cap S| \geq 2^{-1} \} \right)$

(dense S under lines almost entirely in S)

- $S = \text{Nikodym}$ if $\bar{S} = \mathbb{F}_2^n$

- $|S| \geq ?$

Solution [Dvir]:

• Find $Q \in \mathbb{F}_2^{\leq 2^{-2}} [x_1 \dots x_n] \neq 0$ s.t.

$Q(\alpha) = 0 \quad \forall \alpha \in S$

$$Q(\alpha) = 0 \quad \forall \alpha \in S$$

- Claim: such Q exists if $|S| < \binom{n+q-2}{n}$ [counting]

- Claim: if $\ell \in \bar{S} \Rightarrow Q|_{\ell} \equiv 0$
(since $Q|_{\ell}$ is of $\deg \leq q-2$
& $|\ell \cap S| > q-2$)

- $\bar{S} = \mathbb{F}_q^n \Rightarrow Q \equiv 0$

- Contradiction $\Rightarrow |S| \geq \binom{n+q-2}{n} \approx \frac{q^n}{n!}$

State-of-art

General q : $|S| \geq \frac{q^n}{2^n}$

[multiplicities]

Div. Kopparty
- Saraf. S

q of small char: $|S| \geq q^n (1 - o_i(1))$
[Lifted Codes]

[Gino-Kopparty S]

III. Joints Problem [Guth, Katz]

-] = finite set of lines in \mathbb{R}^3

- \mathcal{L} = finite set of lines in \mathbb{R}^3

- $N \equiv |\mathcal{L}|$

- $p \in \mathbb{R}^3 \equiv$ "joint" if

$\exists l_1, l_2, l_3 \in \mathcal{L}$ lin. ind. s.t.

$p \in l_1, l_2, l_3$

- Bound: $J \equiv \# \{ p \mid p \text{ joint in } \mathcal{L} \} \leq ?$

- Trivial Bound: $J \leq \binom{N}{2}$

- Best Example = $K \times K \times K$ grid

$$N = 3K^2 ; J = K^3 = \Omega(N^{3/2}).$$

Guth-Katz Theorem

$$J = O(N^{3/2})$$

Proof: fix $D = 10 \cdot N^{1/2}$

will prove $J \leq (D+1)L$

① Running: - Throw away lines with $\leq D$ joints iteratively

joints iteratively

- At end every line has $> D$ joints.

- Notational Simplicity: $L =$ this set.

② Fix $S \subseteq J$ s.t. every line in L has at least D points of S , but $|S| \leq (D+1)N$

③ Let Q be lowest deg. poly s.t.

$$Q(p) = 0 \quad \forall p \in S.$$

④ Deg $Q = (3(D+1)N)^{1/3} \approx (30)^{1/3} \cdot N^{1/2} < D$

$$(4) \text{deg } Q = (3(D) + N) - \dots$$

$$(5) Q|_L \equiv 0 \quad \forall L \in \mathcal{L} \quad [\text{deg } Q|_L < D ; \\ \triangle Q|_L(p) = 0 \\ \forall p \in L \cap S]$$

$$(6) \text{ let } Q_x = \frac{\partial Q}{\partial x}, \quad Q_y = \frac{\partial Q}{\partial y}, \quad Q_z = \frac{\partial Q}{\partial z}$$

$$Q_\ell = \frac{\partial Q}{\partial \ell}$$

$$(7) Q|_L \equiv 0 \Rightarrow Q_\ell(p) = 0 \quad \forall p \in L \cap S$$

$$\exists 3 \text{ l.i. lines s.t. } Q_{\ell_1} = Q_{\ell_2} = Q_{\ell_3} = 0$$

IV. "Capsets" in \mathbb{F}_3^n

• $A \subseteq \mathbb{F}_3^n$ has a 3-AP if

$\exists x, y, z \in A$ (distinct) s.t.

$$y - x = z - y \Leftrightarrow x + y + z = 0$$

\Leftrightarrow " $\{x, y, z\}$ form a line in \mathbb{F}_3^n "

• Question: if A has no 3-AP.

then $|A| \leq ??$

... 1 Bound. $|A| \leq 3^n$

Trivial Bound: $|A| \leq 3^n$

Roth ... : $|A| \leq 3^{n - \Theta(\sqrt{n})}$

Theorem: [Ellenberg-Gijswijt]

$$|A| < (2.99)^n$$

(Based on Groot-lev-techn analysis in \mathbb{Z}_4^n)

Proof:

⊛ Find Q s.t. $Q(b) = 0 \quad \forall b \in \bar{A}$
, \cap non-zero as often as possible

$\& Q$ non-zero as often as possible
in A .

① Say $T = \{a \mid Q(a) \neq 0\}$

consider $T \times T$ matrix M

with $M(a, b) = Q(-(a+b))$

② A is 3-AP free

$\Rightarrow T$ is 3-AP free

$\Rightarrow M$ is diagonal

$$\Rightarrow \text{rank}(M) \geq |T|$$

③ On the other hand if $\deg Q \leq d$

$$\text{then } M(x, y) = Q(-(x+y))$$

$$= A(x, y) + B(x, y)$$

$$\uparrow$$
$$\deg_y \leq \frac{d}{2}$$

$$\uparrow$$
$$\deg_x \leq \frac{d}{2}$$

$$\Rightarrow \text{rank}(M) \leq 2 \Delta(n, 3, \frac{d}{2})$$

$$\text{Proves } |T| \leq 2 \Delta(n, 3, \frac{d}{2})$$

Proves $|H| \leq 2 \Delta(n, 3, \frac{d}{2})$

But want $|A| \leq \dots$

& need bound on d !

Strategy:

Will set it up such that

$$\dim(\{Q \mid Q(\bar{A}) = 0\}) > \frac{|A|}{2}$$

$$\Rightarrow \exists Q \text{ st. } |\{t \mid Q(t) \neq 0\}| > \frac{|A|}{4}$$

($|A|/4$ easy; $|A|/2$ also..)

$$\Rightarrow |\Pi| > \frac{|A|}{4}$$

$$\dim(\{Q \mid Q(A) = 0\})$$

$$= \Delta(n, 3, d) - |A|$$

$$= \Delta(n, 3, d) + |A| - 3^n > \frac{|A|}{4}$$

\Rightarrow Want d s.t.

$$\Delta(n, 3, d) > 3^n - \frac{3}{4}|A|$$

$$\triangle \text{ get } |A| < 4|T| < 8 \Delta(n, 3, \frac{d}{2})$$

$$\Rightarrow |A| \geq \max_d \left\{ \min \left\{ \frac{4}{3} (3^n - \Delta(n, 3, d)), 8 \Delta(n, 3, \frac{d}{2}) \right\} \right\}$$

Turns out $d \approx 1.98n$ works

$$\text{Prob} \left[\underbrace{e_1 + e_2 \dots e_n}_{e_i \in \{0, 1, 2, 3\}} > (1.98)n \right] \leq \alpha^n \quad \alpha < 1$$

$$\Rightarrow \Delta(n, 3, 1.98n) \geq 3^n (1 - \alpha^n)$$

$$\Rightarrow \text{1st term} \leq \frac{4}{2} (3\alpha)^n$$

$$\text{Prob} \left[\sum e_i \leq .99n \right] \leq \beta^n \quad \beta < 1$$

$e_i, e_n \in \{0, 1, 2\}$

$$\Rightarrow \text{2nd term} \leq \delta (3\beta)^n$$
